StackPath Combined CDN With Edge Computing. Namespace Authority Remained Central.

by [Nick Clark](#) | Published March 28, 2026 | [PDF](#)

StackPath built a unified edge platform combining CDN, WAF, DNS, and serverless scripting at edge locations. The vision was a single platform for all edge services rather than separate providers for each function. The unification is practical. But the namespace that governs all these services — routing decisions, security policies, cache configuration, compute placement — is centrally managed through StackPath's control plane. Unifying edge services did not distribute the authority governing them. The structural gap is between unified edge execution and scope-governed namespace authority.

StackPath's approach of unifying edge services into a single platform reduced the operational complexity of managing separate CDN, WAF, and DNS providers. The integrated approach has genuine value. The gap described here is about governance architecture, not service integration.

Unified services, unified central authority

StackPath's edge platform manages CDN caching, WAF rules, DNS resolution, and edge scripting from a single control plane. Configuration for all services is defined centrally and propagated to edge nodes. A change to a WAF rule, a CDN cache policy, or a DNS record all flow through the same management interface.

The unification means that a single control plane governs more of the edge infrastructure, not less. Where previously each service might have had independent governance, StackPath consolidated governance into one centralized system. The edge nodes execute an increasingly comprehensive set of instructions from the center.

Cross-service namespace without cross-service governance

The namespace that connects CDN routing to WAF policy to DNS resolution operates within StackPath's control plane. There is no mechanism for the namespace to govern cross-service relationships locally. A WAF decision that should affect CDN caching requires the control plane to coordinate. An edge node cannot independently determine that a security event should change its caching behavior.

The cross-service integration exists in the control plane. It does not exist as governed policy at the edge.

What scope-governed indexing provides

A scope-governed index would allow edge regions to govern their namespace segments across all services simultaneously. Local anchors would hold policy covering CDN caching, WAF rules, and DNS resolution for their scope. Cross-service governance decisions would be locally determined through scoped consensus rather than requiring round-trips to the central control plane.

The unified edge platform would continue to provide integrated services. The governed index would add structural authority at the edge, where cross-service decisions can be made locally by the anchors governing each scope.

The remaining gap

StackPath unified edge services into a single platform. The remaining gap is in governance distribution: whether the authority governing those unified services can live at the edge rather than in a central control plane that coordinates everything.
