OneLogin Simplified Enterprise SSO. The SSO Token Is Still a Credential.

by [Nick Clark](#) | Published March 28, 2026 | [PDF](#)

OneLogin simplified enterprise single sign-on by providing a unified portal for accessing applications with directory integration, risk-based adaptive authentication, and SmartFactor authentication. Users authenticate once and receive access to all configured applications. But the SSO model produces session tokens and SAML assertions that are stored credentials with finite lifetimes. A stolen session token provides full access until it expires. The structural gap is between streamlined authentication flows and an identity model where no tokens need to be stored because identity derives from continuous behavioral validation.

OneLogin's approach to simplifying enterprise SSO and its SmartFactor authentication reduced friction for enterprise users. The gap described here is about the SSO model's dependency on session credentials, not about OneLogin's product design.

SSO concentrates credential risk

Single sign-on is valuable because users authenticate once. But the corollary is that the single authentication event produces a session credential that unlocks everything. The SSO session token is the most valuable credential in the enterprise because it provides access to all connected applications.

Session hijacking, token theft, and cookie stealing attacks target SSO sessions specifically because a single compromised session provides broad access. Protecting this concentrated credential is more critical than protecting any individual application credential.

Adaptive authentication adds layers, not elimination

OneLogin's risk-based authentication evaluates context signals before granting access: device fingerprint, IP reputation, login patterns. When risk is elevated, additional authentication factors are required. These are layers of protection around the credential exchange, not elimination of the credential.

After adaptive authentication succeeds, the result is still a session token that must be stored and can be stolen. The authentication was more thorough. The credential it produced is the same structural artifact.

What keyless identity addresses

Keyless identity replaces the session token model with continuous behavioral validation. Instead of authenticating once and receiving a credential, identity is continuously derived from the device's behavioral continuity through trust slope validation. There is no session token to steal because access is continuously validated, not granted and cached.

OneLogin's application integration and directory synchronization would continue to provide the management layer. The identity primitive would shift from token-based sessions to continuous behavioral validation through keyless identity.
